8 Sam says,

"When a number in the 5 times table is multiplied by 5, you always get a number that ends in 5"

(a) Write down an example to show that Sam is wrong.

10 × 5 = 50, which ends in 0.

1 mark

10 is in the 5 times table; this one example disproves the claim.

(1)

Jo says,

"Because 3 and 13 are both prime numbers, all whole numbers that end in 3 are prime numbers."

(b) Is Jo correct?
Give a reason with your answer.

No. 33 ends in 3, but 33 = 3 × 11.

It has factors other than 1 and itself.

1 mark

One non-prime example ending in 3 is sufficient.

(1)

(Total for Question 8 is 2 marks)
